# RESULTS OF CORE DRILLING OF URANIUM-BEARING LIGNITE DEPOSITS IN HARDING AND PERKINS COUNTIES, SOUTH DAKOTA, AND BOWMAN COUNTY, NORTH DAKOTA

By Howard D. Zeller

#### ABSTRACT

A total of 2,450 feet in 19 holes was drilled and 158 feet of lignite core, or an average of 6 feet of lignite per hole, was recovered for uranium determinations on the drilling project conducted during the summer of 1951 and 1852 in northwestern South Dakota and southwestern North Dakota. This report gives the tonnage and grade estimates of uranium-bearing lignite in the areas drilled, the results of 212 chemical uranium determinations, 180 semi-quantitative spectrographic analyses, and 25 proximate and 10 ultimate U. S. Bureau of Mines analyses of the lignite cores. Stratigraphic relationships and correlation of the uranium-bearing lignite cut in the 19 holes are shown by means of charts and diagrams which in addition show in detail the distribution and concentration of uranium in the various lignite beds as well as in the lignite ash.

The data from the drilling program substantiate the theory, developed during the previous field season (Denson et al., 1951) that the uranium in the lignite was secondarily derived by ground water leaching of the tuffaceous sands and bentonitic clays in the overlying White River and Arikaree formations.

Gamma counts recorded with a Berkeley scaler equipped with a Victoreen thyrode tube and 400-foot coaxial cable showed marked radioactivity in the

CONTINUE TA

olite

White River-Arikaree source beds, which unconformably overlie the uraniumbearing lignites at Slim Buttes.

Spectrographic analyses of the ash from the lignite cores reveal that molybdenum closely parallels uranium in distribution and concentration and may possibly be significant as an indicator element in prospecting for uranium.

#### DRILLING OPERATIONS

#### Purpose

The main objective of the Dakota core drilling program was to determine reserves of uraniferous lignite based on chemical uranium and spectrographic determinations from unweathered samples, particularly from those areas where surface sampling of the beds during the previous field season indicated that significant deposits of uranium-bearing lignite might be present. A secondary objective was to obtain fresh samples and to measure the radioactivity of the overlying Oligocene White River and Miocene Arikaree formations from which the uranium in lignite is believed to have been derived.

#### Areas drilled

Core holes were drilled in four major areas: the Mendenhall and Bar H areas, Slim Buttes, Harding County, South Dakota; the Lodgepole area, Perkins County, South Dakota; and the Medicine Pole Hills area, Bowman County, North Dakota. Holes also were drilled in the Johnson outlier area, Four of the near the Lodgepole area. The eight holes drilled in the Slim Buttes area

## SPAIDT TWO TWANTEN

8

holes are on privately owned land. The locations of these areas are shown on figure 1.

Seven hales were drilled in the mendenhallana, Slim Bytten, Handing Country, S.D. (fig. 1) in 1951, the results of that drilling are presults Drilling contract by J.R. 6:11 in Chapter ...

The drilling was done by the B. H. Mott Drilling Company, Huntington, West Virginia, under contract I gs-12521, dated May 18, 1951. Work commenced on June 11, 1951, and was discontinued on November 21, 1951, owing to the onset of winter.

Contract prices were as follows:

Core drilling 0-400' Solid bit drilling 0-200'

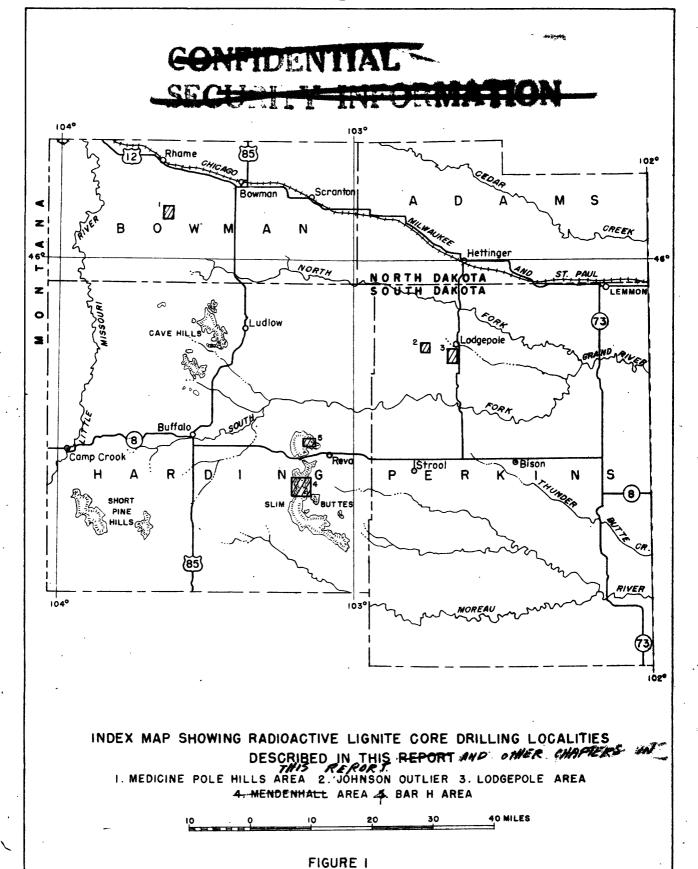

\$3.90 per foot 3.65 per foot

The contract called for NX cores (2-1/8"); however, the contractor used bits that furnished 2-1/4" lignite cores. A core recovery of 80 percent or more was stipulated in the contract for all lignite beds drilled. The total footage drilled to date is 2,486 feet at a drilling cost of \$9,375.40.

#### Equipment

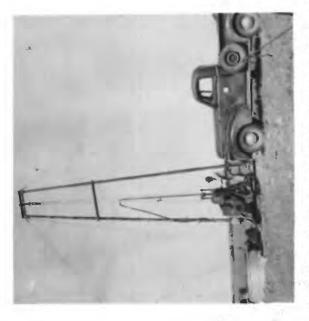

Holes 1 through 16 were drilled with a special Mott Company drill employing a Sullivan Hoist and powered by a Case tractor engine, which is the approximate equivalent of a Sullivan 22 drill. The derrick was hydraulically raised and lowered and the rig was mounted on dual tires and pulled by the water truck (fig. 2A). Holes 17 through 19 were drilled with a smaller skid-mounted drill powered by a Wisconsin air cooled engine. This drill, also made by the Mott Drilling Company, was equipped with a Sullivan hoist and is similar to a Sullivan 12 drill. The derrick consisted of two steel

A. Trailer-mounted drill, Mott Drilling Company, Hole No. 4, Slim Buttes, South Dakota.

poles and a cross member and was guyed to the ground by cables (fig. 2B).

For the deep drilling on Slim Buttes (300' or more) the larger, more powerful drill was less affected by caving of the loose sands at the top of the
White River formation.

Three different lengths of core barrels were used: 5, 10, and 15 foot. A tungsten carbide-faced sawtooth bit was found to be the most successful in coring the "gummy" clays and "rubbery" lignites. A diamond bit served satisfactorily for coring some of the harder lignite but proved unsatisfactory in drilling through the clay. The solid bit drilling was done with a Hawthorne "Blue Demon" rock cutter bit.

A Bean Royal reciprocating water pump was used for all of the drilling. Casing was used only in the upper 5-20 feet of each hole, and no cementing was done.

#### Drilling progress

It was originally estimated that three months would be sufficient time to complete the drilling. Nearly twice that amount of time was required, however, due to caving in many of the holes and loss of water circulation.

Water circulation was lost at a depth of about 100 feet in each of
the 4 deep holes on Slim Buttes. In three of these holes artesian water
was encountered in a loose porous sand near the top of the White River formation. The water rose to within 50-100 feet of the surface where it
flowed out through fractures and joints in the well indurated sandstone
lenses of the overlying Arikaree formation. The loose porous sand near
the top of the White River formation was the horizon in which caving was

SECURITY INFORMATION

most pronounced. It was not uncommon to have to redrill 100 feet or more after a 15-hour lapse in drilling. Bentonitic clays (10-20 feet thick) overlying the sand also tended to work back into the hole and clog the core barrel as it was lowered through this zone to the lignite. These clays commonly swelled in the core barrel. It was necessary many times to spend 3 to 4 hours in removing the core from the barrel.

About 2,000 gallons of water were needed per 8-hour shift in the deeper holes on Slim Buttes. This water had to be hauled 4 to 6 miles over roads that were practically impassable during wet and snowy weather. The unusually wet weather from September through November greatly handicapped the drilling.

Some of the lignite in the shallow holes was weathered, and it was only because of the driller's competence and experience that he was able to get such high recovery (90-100 percent). A 7'10" soft weathered lignite in Perkins County was cored with 100 percent recovery by using little or no water and forcing the core barrel through the bed as fast as possible.

No attempt was made to calculate the number of feet drilled per 8-hour shift. The primary objective was to get good lignite cores that could be studied and analyzed and this was successfully accomplished.

#### Recommendations for drilling procedure

In the event that additional core drilling is undertaken on Slim Buttes, certain recommendations are here submitted. The drilling would progress faster if the drill rig was mounted on a truck to increase its mobility in many areas where the land is intensely cut up by streams and

high

and also prevent some loss in water circulation in drilling the Arikaree and White River formations. The holes should be cased through the entire thickness of the Arikaree and White River formations to eliminate the caving hazard. A rock bit of the roller type would also be helpful as most fish tail bits will not cut the hard siliceous layers in the Arikaree sandstone.

#### GEOLOGY

#### Previous work

During the summers of 1911-12 Winchester et al. (1916) mapped the lignite deposits of Harding and Perkins Counties, South Dakota, to classify the land into coal and non-coal lands. Hares (1928) mapped the lignite resources of the Marmarth Field, southwestern North Dakota, during the same period. Darton (1909), Toepelman (1923), and Wood (1942) have also briefly described the geology of small areas within Harding and Perkins Counties. Uranium-bearing lignite in this region was described by Wyant and Beroni (1950).

As a part of the Trace Elements program of the U. S. Geological Survey, Denson, Bachman, and Zeller (1951) investigated the uranium-bearing lignites in Harding and Perkins Counties, South Dakota, and in the adjoining area of the Medicine Pole Hills in Bowman County, North Dakota, en behalf of the U. S. Atomic Energy Commissions. Individual maps, showing the extent, thickness and variation in mineral content of the various deposite, were submitted with estimates of petential underground and strippeble resources.

#### Acknowledgments

To James M. Schopf, U. S. Geological Survey Geel Geology Laboratory, Columbus, Ohio, much credit is due for helpful suggestions in the field and for the detailed descriptions of the lignite core. (See appendix C of this report.) William G. Pierce, Chief of the Mostern Field

investigations, Fuels Branch, visited the project and gave helpful counsel. Andrew Brown of the U. S. Geological Survey's Coal Section spent one week with the project at the beginning of the drilling and gave valuable assistance on drilling problems that developed. William W. Vaughn, Chief of the Radiation Instrument Group, U. S. Geological Survey, spent a day with the writer in the field explaining the operation of a gamma ray logging device that was used in the deep holes on Slim Buttes; his help was greatly appreciated. The project was also visited in conjunction with a conference on uranium-bearing lignites by the following men whose suggestions and advice were much appreciated: Theodore Botinelly and Maurice Deul, Trace Elements Section, Geochemistry and Petrology Branch, U. S. Geological Survey; Farrington Daniels, Department of Chemistry, University of Wisconsin, Madison, Wisconsin; and Donald Peppard, Chemistry Division, Argonne National Laboratory, Chicago, Illinois. The results of the investigation would not have been possible without the analytical data on the lignite cores furnished by John C. Rabbitt, and staff of the Brace Elements Section Washington laboratory, Goodhamistry and Detrology Branch U. S. Geological Survey.

This work is part of a program of exploration for radioactive raw motorials undertaken by the U. S. Geological Survey on behalf of the U. S. Atomic Energy Commission. The work was carried out under the general supervision of N. M. Denson.

#### Areas drilled

#### Introduction

No attempt is made in this report to describe the geology in detail. Only a brief statement on each area is included. A detailed account of the regional geology may be found in Winchester et al. (1916), and Hares (1928). For details on the geology and origin of the uranium-bearing lignite in the areas (here described the reader is referred to Denson et al, In summary, Denson et al. (1950) postulated that the uranium had been leached from the tuffaceous sediments of the overlying White River and Arikaree formations, carried in solution by ground water, and later adsorbed by the underlying lignite. Geologic factors controlling the distribution of uranium in the Dakota lignites were believed to be the stratigraphic proximity of the lignite to the base of the White River formation, permeability of rocks overlying the lignite, adsorptive properties and the porosities of the lignite constituents, present and past position of the ground water table, and the amount of uranium indigenous in the original White River and Arikaree sediments. The results obtained by the preciated by Donson! core drilling in the Dakotas, substantiate theory in most respects. It is to be emphasized that generally the analyses of the lignite cores show the higher concentrations of uranium in the upper part of radioactive beds three feet or more in thickness, the uranium content decreasing downward to near the vanishing point in succeeding lower beds. (See figures and 19 showing distribution and concentration of uranium in lignite cores.)

SECURITY

## SECURITY INFORMATION

18

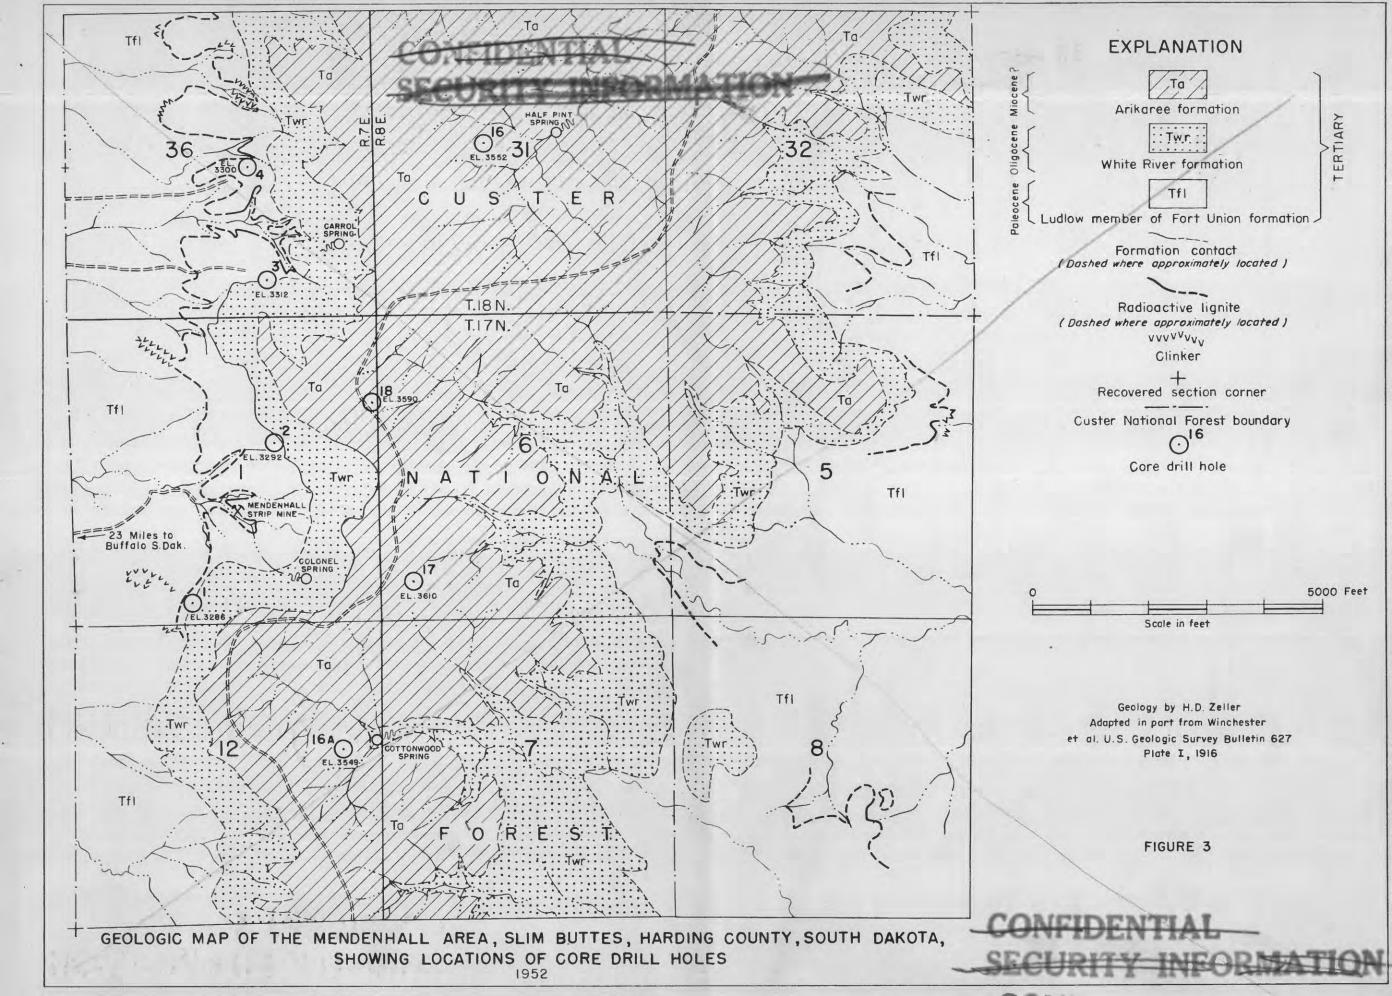

#### Mendenhall area

General description.—The Mendenhall area lies in the central part of Slim Buttes about 4 miles north of J-B pass and 4 1/2 miles south of Reva Gap, in southeastern Harding County, South Dakota. The area is most easily accessible along the top of the Buttes by a U. S. Forest Service road that extends north from the J-B pass road half a mile east of the divide. The Mendenhall strip mine (fig. 3) on the west side of Slim Buttes is accessible by a secondary county road extending south from State Highway No. 8, 12 miles east of Buffalo. Seven miles south on this county road a dirt road extends east 4 miles to the mine. The pearest railroad shipping point is Bowman, North Dakota, 70 miles to the north.

The bedrock in the Mendenhall area consists of three formations which are essentially horizontal. The oldest is the lignite-bearing Ludlow member of the Fort Union formation of Paleocene age which crops out along the base of the Buttes. The Ludlow member consists predominantly of soft, light-buff, and tan-gray sandstone, shale, and lignite and is unconformably overlain by 340 feet or more of chalky gray tuffaceous sandstone and bentonitic clay of the White River formation of Oligocene age and the Arikaree formation of Miocene age. The Arikaree formation stands in imposing cliffs 200 feet high along the margins of Slim Buttes, which rise 300 to 400 feet above the surrounding county.

The accompanying map (fig. 3), compiled from aerial photographs, shows the locations of the drill holes and the areal distribution of the rock units described above. The two main lignite beds in the area are referred

to here as the Mendenhall and Olesrud beds (figs. 4 and 5). The Mendenhall lignite bed ranges in thickness from 7 to 15 feet and is separated from the underlying Olesrud bed by 2 to 20 feet of clayey shales. Both beds have their maximum observed thickness in hole 3 (fig. 5) where each is 15 feet thick.

Distribution and concentration of uranium.—Analyses of the cores from the 7 holes penetrating lignite beds in the Mendenhall area show quite distinctly that the uranium is concentrated in the upper 5 feet of the stratigraphically highest lignite bed below the base of the White River formation (fig. 5). The uranium content decreases downward almost to the vanishing point within an interval of 5 feet.

In 6 of the 7 holes drilled in the Mendenhall area, the Mendenhall bed is the stratigraphically highest lignite, and it contains a higher percentage of uranium than any of the other beds cored lower in the section. In hole No. 4 the Mendenhall bed is non-radioactive; it is believed that this is due to the presence of a higher lignite bed which occurs 44 feet above it. This higher bed, referred to as the Mendenhall "rider," consists of three seams separated by shale. The upper seam has a higher concentration of uranium than any other lignite cored. In the area drilled the Olesrud bed, which underlies the Mendenhall bed, was not found to contain more than 0.001 percent uranium.

Quality of lignite. -- The Mendenhall bed is a high quality lignite which is second only to the Harmon bed drilled in the Lodgepole area.

An average of 13 Bureau of Mines analyses shows the bed to contain, on an air dried basis, approximately 38 percent fixed carbon, 13 percent ash,

## SECURITY THEORY TION

21

1.7 percent sulphur, and a heating value of about 8,420 Btu. The lignite in the Olesrud bed is of only slightly poorer quality than the Mendenhall lignite; analyses on an air dried basis show approximately 37 percent fixed carbon, 13 percent ash, 1.6 percent sulphur, and a heating value of about 8,380 Btu. The Mendenhall "rider" bed is a much poorer grade of lignite; it contains, on an air dried basis, about 20 percent fixed carbon, 31 percent ash, 2.8 percent sulphur, and has a heating value of about 4,500 Btu.

Substitute discussion from
TENR 342
Bar H area p. 8,9,11,12,

General description. -- The Bar H area is at the northeastern tip of Slim Buttes in -central Harding County, South Dakota (fig. 1). Radio-active lignites in the Ludlow member of the Fort Union formation of Paleo-cene age crop out along the north base of the Buttes. The outcrops are accessible only from the top of the Buttes by 6 miles of Forest Service dirt road that joins State Highway 8, 2 miles west of Reva.

The geology of the area is similar to that of the Mendenhall area except that the lignite-bearing beds are broken by a fault of pre-White River age. The fault trends N. 75 W. for an inferred distance of about a mile and has a maximum stratigraphic displacement of about 150 feet. Drag dips resulting from the downward movement along the south side of the fault are quite noticeable. On the south side of the fault the nearly horizontal beds of the White River formation truncate the steeply dipping lignite-bearing rocks of the Ludlow. The lignite-bearing beds are nearly horizontal 500 feet away from the fault and from surface exposures appear to

be essentially horizontal throughout most of the area.

The Bar H lignite bed is believed to be the stratigraphically highest persistent bed over most of the area, although in some places a thin "rider" bed lies 60 feet or more above the main Bar H bed. The Bar H bed has an average thickness of about 12 feet and is exposed at many places along the north base of Slim Buttes. In the only core hole drilled in the Bar H area (hole 19, figs. 4 and 5), the "rider" bed was the only lignite bed cored. In the core hole the "rider bed" consists of three beds each about 2 feet in thickness and separated by 2-foot beds of sandstone and shale. A bed of carbonaceous and coaly shale 6 inches thick and about 34 feet above the Bar H "rider" is not considered part of the "rider."

<u>Distribution and concentration of uranium</u>.—Uranium is distributed in the Bar H "rider" in the pattern observed in most of the other lignite beds, with the highest concentration in the upper of the three seams of the "rider," and decreasing in the lower two.

Quality of lignite.—According to analyses made by the U. S. Bureau of Mines, the three beds making up the Bar H "rider" in hole 19 contain, on an air dried basis, an average of 36.5 percent fixed carbon, 22 percent ash, 1.3 percent sulphur, and have a heating value of 8,230 Btu.

#### Lodgepole area and Johnson outlier

General description. -- The Lodgepole area and the Johnson outlier are in northwestern Perkins County, South Dakota. The areas are readily accessible by 17 miles of graveled road extending north from State Highway 8 about 9 miles west of Bison. Hettinger, North Dakota, the nearest shipping

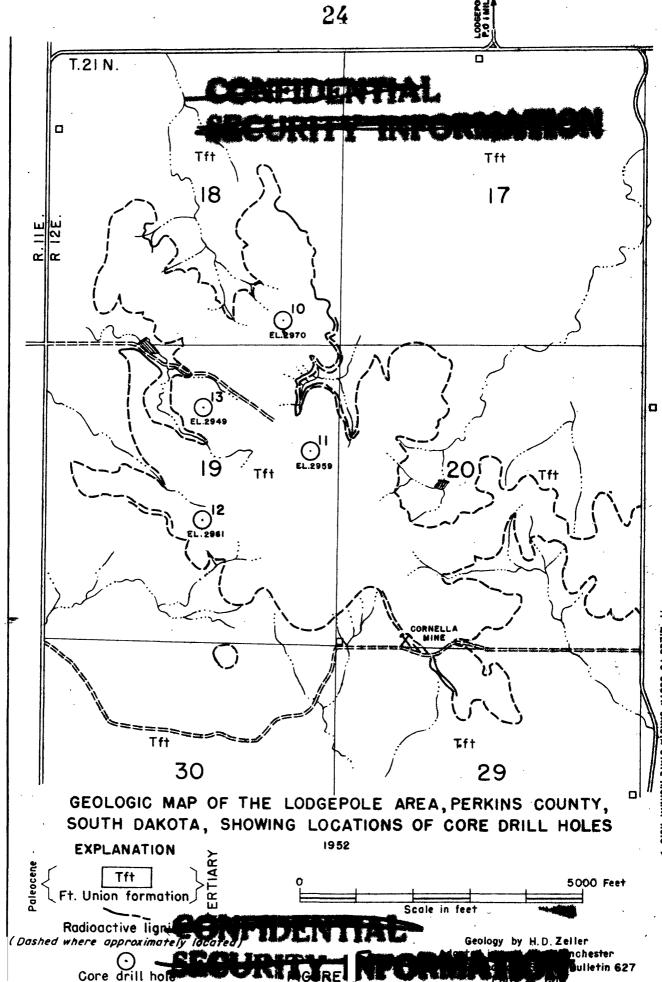

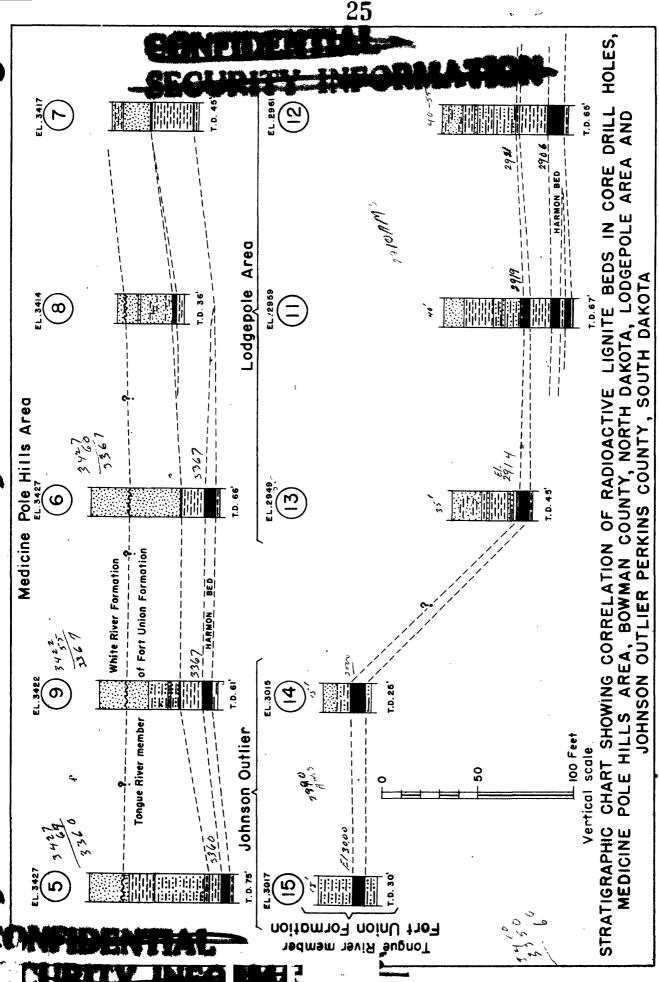

point is 17 miles to the north (fig. 1). A low grassy butte a mile south of Lodgepole Post Office is the main topographic feature in the Lodgepole area. A similar butte referred to in this report as the Johnson outlier is 5 miles to the west. The lignites in both areas were mapped and described by Winchester (1916, p. 138, 142). A map, compiled from aerial photographs at a scale of 1:20,000 (fig. 6), shows the areal distribution of the lignite and the location of the drill holes in the Lodgepole area. Because the reserves were small and aerial photographs were not available, a map of the Johnson outlier was not prepared.

The radioactive lignite in these areas occursabout 150 feet above the base of the Tongue River member of the Fort Union formation of Paleocene age which has a regional dip of about 24 feet per mile NE. The dominant lithologies of the Tongue River member are soft gray to pink sandstone and siltstone with interbedded gray shale and lignite. The main lignite bed averages 6 feet or more in thickness and is believed to be the Harmon bed (fig. 7). It commonly is associated with a "rider" bed 10 to 15 feet stratigraphically higher which ranges from a few inches to 6 feet in thickness in short distances along the outcrop. The bed in the Johnson outlier may be either the Harmon bed or its "rider."

Distribution and concentration of uranium.—The lignite cored in holes 11, 12, and 13 in the Lodgepole area contain only a small percentage of uranium. Only the upper 1 to 2 feet of the Harmon rider contain over 0.001 percent chemical uranium while the underlying Harmon bed was non-radioactive. The lignite on Johnson outlier, however, contains significant amounts of uranium (fig. 3). Uranium analyses showed concentrations in

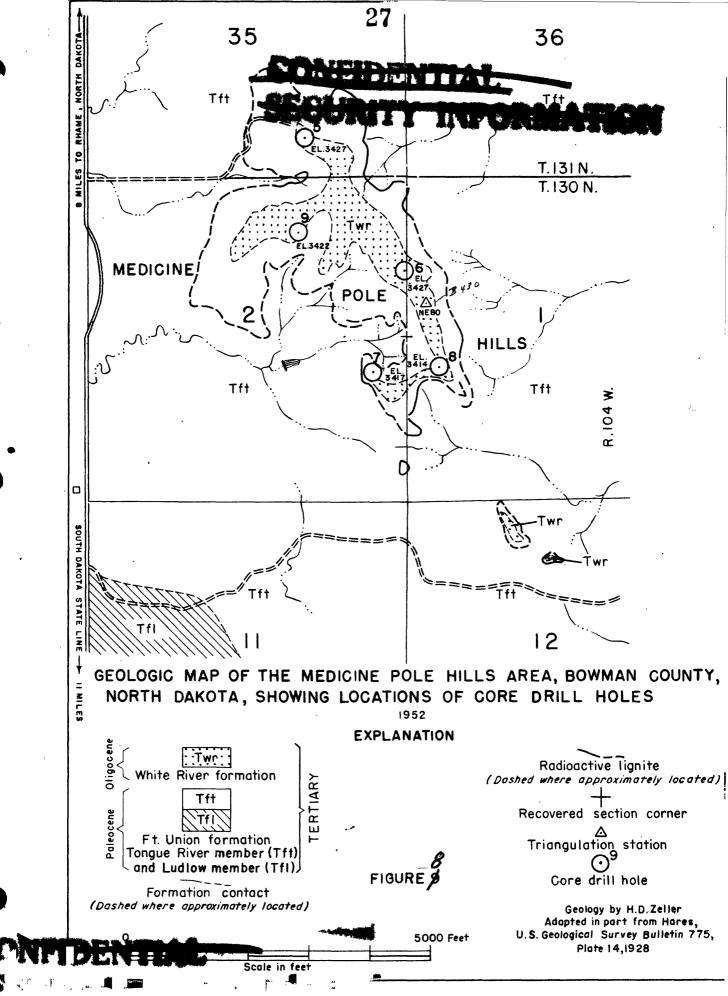

hole 14 of 0.036 percent which diminished downward to 0.001 percent,  $3\frac{1}{2}$  feet from the top of the lignite bed. The analyses of the lignite core from this hole demonstrates ideally the pattern of distribution and concentration in most of the radioactive lignite beds sampled in 1950. (Demon state),

Quality of lignite. -- The lignite in the Harmon bed of the Lodgepole area, on an air dried basis, averages about 36 percent fixed carbon, 12 percent ash, 1 percent sulphur, and has an average heating value of 9,230 Btu. This is the best grade of lignite found in drilling. On Johnson outlier the lignite is of a poorer quality; on an air dried basis it averages about 24 percent fixed carbon, 18 percent ash, 2 percent sulphur, and has a heating value of 6,170 Btu.

#### Medicine Pole Hills area

General description.—The Medicine Pole Hills in Bowman County, North Dakota, are on a hilly divide separating the Little Missouri River and Grand River drainage basins. In the mapped area (fig. 9) the hills are capped by a thin veneer of the White River formation of Oligocene (Chadronian) age (Gazin, 1950). The hills are outlined by ledges of hard sandstone and quartzite in the Tongue River member of the Fort Union formation of Paleocene age, which is unconformably overlain by the White River formation. The hills are nearly flat-topped and are easily accessible by a dirt road leading half a mile east from the main north-south graveled road to Rhame, North Dakota. The nearest railroad shipping point is at Rhame, 8 miles to the north. The Medicine Pole Hills area is in the southwestern

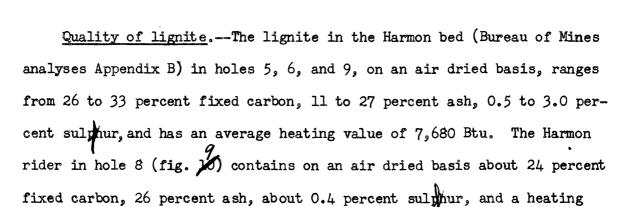

part of the Marmarth lignite field, which was mapped and described in detail by Hares (1928, p. 95, 98).

A widespread persistent lignite, the Harmon bed, underlies most of the area (fig. 7). This bed and its associated "rider" were mapped by the on aerial photographs at a scale of approximately 1:20,000. The accompanying map, compiled from the photographs (fig. 7), shows the locations of the drill holes which penetrated the radioactive Harmon bed in the Medicine Pole Hills area.

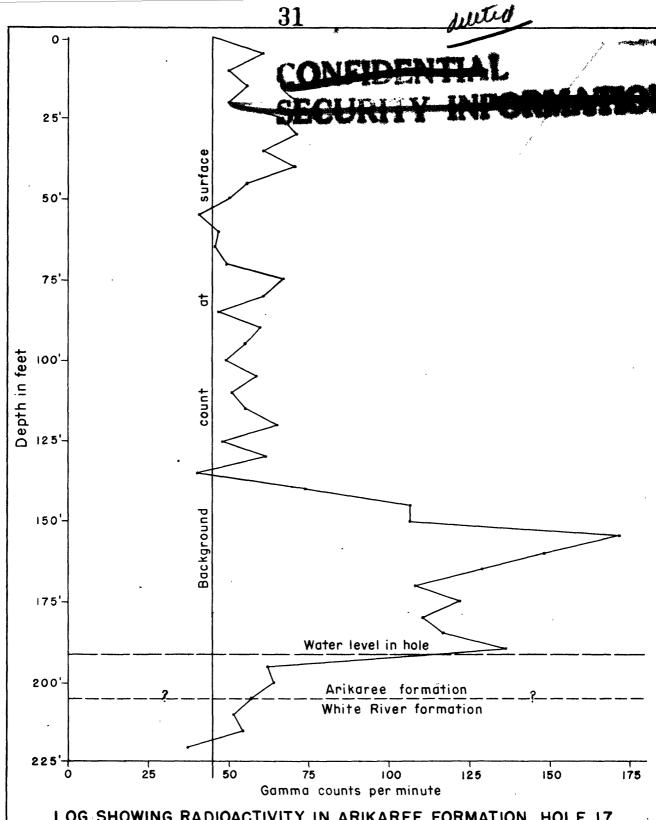

Distribution and concentration of uranium. -- The concentration and distribution of uranium in the lignite cores from the Medicine Pole Hills differ from the general pattern observed in other areas. The distribution of uranium in core hole No. 5 (fig. 1) follows the general pattern in which the concentration of the uranium diminishes progressively from the top of the lignite downward. In holes 6 and 9, however, the uranium content is fairly uniform throughout the bed with perhaps a slightly greater concentration at its base. This distribution has not been observed in radioactive lignites elsewhere, either in cores or surface samples. The Harmon "rider" bed is 30 inches thick in hole No. 8 and contains 0.005 percent uranium in the upper 6 inches and 0.016 percent uranium in the basal foot of the bed. This "inverted" pattern is a very common feature in radioactive lignite beds  $2\frac{1}{2}$  feet or less in thickness throughout the region where they have been examined in the Dakotas. A possible explanation for the higher concentrations of uranium in the lower rather than the upper parts of these beds might be that mineralizing ground waters have moved laterally along the base of thin and fractured lignites normally overlying impervious underclays.

Radioactivity in the White River and Arikaree formations and following this handfured + 6.115 report

value of 5,880 Btu.

A Berkeley scaler equipped with a Victoreen thyrode tube and 400-foo coaxial cable was used to measure the radioactivity of the White River-Arikaree source beds unconformably overlying the uranium-bearing lignites on Slim Buttes. Unfortunately most of the holes caved in soon after the lignite was cored and a complete record of the radioactivity in all of the holes penetrating the White River and Arikaree formations was not obtained. The most complete radioactive log obtained by the method described above was in hole 17, the gamma counts of which are plotted and shown in figure 11. Although the Arikaree formation is lithologically uniform throughout the drill hole, the radioactivity is above background throughout most of the hole and is notably higher near the base of the Arikaree formation. As water was encountered in the hole a few feet above the White River-Arikaree contact, readings through the White River could not be calibrated for comparison with those taken higher in the section. reason for the apparently higher concentration of uranium or other radioactive elements near the base of the Arikaree sandstone may be due to the

SECTIFIED THE SEMANDON

occurrence of a widespread and persistent 10- to 40-foot thick bed of impervious bentonitic clay at the top of the White River formation which supports a perched water table.

It may be significant that gamma counts recorded in three of the four deep holes showed a similar higher concentration of radioactivity in the lower part of the Arikaree formation. Leaching of uranium from the upper part of the Arikaree formation and concentration of uranium in the lower part of the formation, which seems uniform lithologically, is suggested but cannot yet be confirmed.

#### Relationships between uranium and other trace elements in Dakota lignites

Semi-quantitative spectrographic determinations were made on the ash from most of the Dakota lignite core samples to determine the vertical distribution and possible relationship of uranium to other trace elements. The results of these analyses are tabulated in appendix A to show the position and thickness of the sample, percent of ash, and the amount of chemical uranium in relation to the amounts of other elements present as determined by spectrographic analysis.

Preliminary work on the occurrence and distribution of the various elements determined by spectrographic analyses indicated that only one element, molybdenum, shows a consistent relationship to uranium. In the upper part of the beds where the uranium content is usually high, the molybdenum content is also high and conversely in the lower part of the beds where the uranium is usually low, the molybdenum is also low. The notable correlation between the uranium and molybdenum contents in various

parts of radioactive lignite beds is believed to be due to the close chemical similarity of these elements (Clarke, 1924, p. 722).

There is no apparent correlation between the occurrences of uranium and vanadium in Dakota lignite although these elements commonly occur together in the deposits of the Colorado Plateau. Their chemical makeup, however, does not seem to indicate that the two would necessarily be expected to occur together.

The net result of the preliminary spectrographic studies of radioactive lignite to date seems to indicate that greater importance and attention might be given to the occurrence of molybdenum as a possible geologic indicator for uranium. Considerably more data and work are necessary along this line of investigation, but it seems possible that the association noted above may prove valuable in the search for uranium.

#### RESERVES

#### General statement

the areas described in this report in

On the basis of drilling done so far in morthwestern South Dakota and a, e, e coo southwestern North Dakota there are inferred reserves of about 16,000,000 tons of recoverable lignite. containing about 1,000 tons of uranium. (See page 36.). Approximately half of these inferred recoverable reserves are suitable for strip mining and are in beds averaging more than 4 feet in thickness. Analyses of 200 samples from drill cores in addition to 175 surface samples from the previous season's field work indicate that the uranium content of the lignite included in these reserves averages about 0.009

percent. The average grade of the uranium in small parts of the areas for which reserves were estimated may be as high as 0.03 percent. The ash content of the lignites ranges from 10 percent or less to about 20 percent, which indicates that the uranium content in the ash is at least five times and generally seven to ten times that of the lignite. Proximate and ultimate analyses show a sulphur content of 2 percent or less and heating values of about 8,200 Btu. (air dried).

#### Plans

The radioactive lignite deposits underlying Slim Buttes in Harding County, South Dakota, are perhaps the most promising of those areas examined in the Dakotas. These lignites average 10 feet or more in thickness and are in close stratigraphic proximity to the base of the White River formation which is thought to be the source of the uranium now found in the lignite. The available core data are incomplete, however, to accurately appraise the area's potentialities. The drilling program undertaken during the 1951 field season was recessed in the fall before completion of the contract. When weather conditions permit, it is planned to continue this program for the total of about 800 feet remaining in the contract.

At the present time, no other work except for the completion of the final report is planned for this region. However, if present rumors to the effect that a power plant is to be built in this general area become more definite, a program for additional reconnaissance and drilling may be proposed at a later date to appraise more accurately the lignites that possibly might be used as fuel.

## APPENDIX C

LITHOLOGIC DESCRIPTIONS OF DAKOTA LIGNITE CORES

BY JAMES M. SCHOPF, U. S. COAL GEOLOGY LABORATORY, COLUMBUS, OHIO.

Lignite core description by James M. Schopf, U. S. Geological Survey Coal Geology Laboratory, Columbus, Ohio

SLIM BUTTES, HARDING CO., S. DAK. Mendenhall area

Hole 1

Location: SE-SE-SW-1-17N-7E Elevation: 3,286 feet

Date cores: 6/15-25/51 Date described: 8/7-8/51

19' 6"

Clay, yellow, silty; grading to siltstone at 19' 8\frac{1}{4}", grading to clay, silty, brown, with streaks of yellow silty clay, (not sampled).

20' 8"
Loss in coring 2' 8".
23' 4"

Clay, light buff, (not sampled). 24' 1"

Shale, clayey, brown, with yellow clay streaks, (not sampled).  $24^{\circ} 2^{\frac{1}{L}}$ 

Shale, black, (not sampled).

25'  $9\frac{1}{2}$ " Clay, gray, (not sampled).

Loss in coring 1' 2".

271 511

TE sample No. 1 (.001U)\*

35' 8"

Coal, moderately woody, 1½" wood band at 35' 11-3/4", ) Lab. No.

pyritic streak at 35' 11¼", core broken. TE sample

No. 2

36' 4" -----)
Loss in coring 10".

37' 2"
Coal, complete interval TE sample No. 3

37' 3年"
Clay, gray, with carbonaceous streaks, grading to dark gray, (not sampled)。

\* Numbers in parentheses following T.E. samples refer to percent uranium in the sample. Where no number appears the uranium content is less than 0.001 percent.

```
Hole 1 (cont.)
37'115"
     Shale, black, (not sampled).
381 1"
     Coal, abundantly woody. Complete interval TE sample No. 4.
     (.002 U)
381 2½11
     Clay, dark gray, (not sampled).
     Shale, clayey, (not sampled).
38 7法"
     Coal, badly broken, probably attrital, 🖠 sent to Bureau)
     of Mines and \frac{1}{2} sent to TE. TE sample No. 5. (.001 U).
     Coal, attrital, with a few woody streaks in lower part,
     badly broken. TE sample No. 6.
401 3/41
     Coal, attrital, with a few sparse woody streaks, thin
     fusain streaks at 44! 2-3/4!, 40! 5!, 40! 6\frac{1}{2}! and 40!
                                                                 Bureau of
     9-3/4"; white mineral blebs at 40' 3", 40' 5\frac{1}{2}" and
                                                                 Mines
     40' 10±". TE sample No. 7.
                                                                 sample Lab.
411
                                                                 No. D-68848
     Coal, moderately woody streaks in upper part; 4\frac{1}{2} solid)
     wood at 41' 2½", abundantly woody in lower part; white
     mineral blebs at 41' 9\frac{1}{4}". TE sample No. 8.
     Coal, sparsely woody streaks; lower part moderately
     woody white mineral blebs at 42' 14". TE sample No. 9.
42'11-3/4"
     Clay, gray, with a few carbonaceous streaks, (not
     sampled).
43 4분비
     Coal, moderately woody, broken. TE sample No. 10.
     (.001 U).
43 8計
     Clay, silty, gray, with carbonaceous bands, (not sampled.)
448
General Notes: There was considerable loss in coring in this hole.
of the recovered core appears suitable for microscopic preparation; how-
ever one-third of the core has been reserved in Columbus, Chio for special
study or reference if needed.
Bureau of Mines Sample D-68847:
                                   Interval 34' 8" to 36' 4"; Loss 0";

Hole 2

Location: SE\_SW\_NE\_1\_17N\_7E Elevation: 3,292 feet

Date cored: 6/28/51 Date described: 8/7/51

Coal, badly broken, moderately woody, TE sample No. 1 (.038U).

511 511

Clay, dark gray, (not sampled).

51'  $6\frac{1}{2}$ " Coal, abundantly woody, badly broken. TE sample No. 2, (.017 U).

51'11-3/4"

Clay, gray with sparse wood bands, (not sampled).

52' 6<sup>1</sup>/<sub>4</sub>"

Coal, abundantly woody, broken into biscuits. TE sample No. 3, (.006 U).

53' 4-3/4"

Coal, abundantly woody, broken into biscuits. TE sample No. 4, (.010 U).

53'10"

Coal, abundant woody bands, badly broken into biscuits. TE sample No. 5, (.007 U).

54.110"

Coal, moderately woody, badly broken into biscuits. TE sample No. 6, (.005 U).

55'10"

Coal, abundant woody bands, badly broken. TE sample No. 7, (.013U).

561 9분배

Coal, abundant woody bands, badly broken. TE sample No. 8, (.006 U).

57' 9분"

Coal, dominantly woody, badly broken. TE sample No. 9, (.004 U).

581 8m

Coal, pulverized, core incoherent. TE sample No. 10, (.003 U).

59 1 1"

Loss in coring 1' 5".

601 611

Coal, pulverized, incoherent core. TE sample No. 11, (.002 U).

Bureau of Mines sample Lab. No. D-68851

Hole 2 (cont.)

61 1 911 Clay, dark gray, with a few woody coal streaks; 12" of impure woody coal at 62' 6" and 1'  $1\frac{1}{2}$ " at 64' 4". Clay, dark gray, with thin carbonaceous streaks. 651 4号11 Coal, attrital, with sparse woody bands. TE sample No. 12. 661 AFI Coal, attrital, with sparse woody bands. Lower part moderately woody, badly broken. TE sample No. 13 Bureau of 671 3-3/4" )Mines sample Coal, pulverized, core incoherent. TE sample No. 14. )Lab. No. 681 4号11 )D-68850 Coal, pulverized, core incoherent. TE sample No. 15. 691 611 Coal, attrital, with sparse woody bands, thin impure streak at 69' 64", core badly broken. TE sample No. 16. Coal, probably attrital, evidences of impure streaks, core broken and dry. TE sample No. 17. 711 6"

General Notes: No section of the core appears suitable for microscopic preparation; however, one-third of the core has been reserved in the Coal Geology Laboratory at Columbus, Ohio for special study or reference if needed.

Bureau of Mines Sample D-68851: Interval 51' to 61' 9"; Loss 1' 5"; Rejected 8"; Coal in sample 8' 8".

Bureau of Mines Sample D-68850: Interval 65'  $4\frac{1}{2}$ " to 71' 6"; Loss 0"; Rejected 0"; Coal in sample 6'  $1\frac{1}{2}$ ".

SLIM BUTTES, HARDING CO., S. DAK. Mendenhall area

Hole 3

Location: Near c SW-SE-36-18N-7E Elevation: 3,312 feet

Date cored: 7/6/51 Date described: 8/3/51 and 8/4/51

871

Clay, with ferruginous pebbles, etc., possibly caved from above,  $l\frac{1}{2}$ , followed by gray silty clay with fine "soapy" texture grading into gray clay shale and reverting to silty clay at about 87' 8";  $\frac{1}{2}$ " hard pyritic sandstone lens at 87'  $10\frac{1}{2}$ "; clay beneath, dark gray, wavy bedded with some thin light gray layers and lenses, lower part slightly darker and more uniform in texture, (not sampled).

88'  $7\frac{1}{2}$ " (top of coal)

Coal sparsely thin—and medium-banded, attrital coal, earthy texture, core considerably cracked and broken.

TE sample No. 1 (.004 U).

891 7-3/4#

Coal, platy and cracked, probably medium-banded above, lower portion incoherent, weathered (?), split and badly broken. TE sample No. 2 (.003 U).

901 7-3/4"

Coal as above, platy fragments with some earthy pieces) D-68853 TE sample No. 3, (.003 U).

911 7号11

Loss in coring and handling (?)  $4\frac{1}{2}$ .

921

Coal, mostly attrital, thin layered,  $\frac{1}{2}$ " shaly parting at the top of this section (not rejected); appears sparsely woody but determination uncertain. TE sample No. 4. (.001 U).

92110点1

Coal, more woody than above, trace of fusain, core fairly coherent but dry. TE sample No. 5.

93110計

Coal, moderately woody, thin- and medium-banded; fusain lenticles, numerous between 94' 3" and 94' 5"; core coherent but dry. TE sample No. 6.

94'10"

Coal, sparsely woody, thin- and medium-banded, fusain lens at 95' ½". TE sample No. 7.

951 2-3/41

Shale, clay, upper inch dark gray, grading below to olive gray, becoming silty below 95' 6", grading into argillaceous siltstone with a few coaly streaks, sandy beneath 96'; sandy beds contain thin carbonaceous streaks; becomes more clayey and carbonaceous below 97' approaching the coal.

Bureau of Mines sample Lab. No. D-68853

```
Hole 3 (cont.)
 97' 4"
      Coal; core fairly coherent but platy and fractured and)
            1 fusain zone beneath 97' 5-3/4"; white mineral)
      blebs (kaolinite?) at 97' 8\frac{1}{2}". TE sample No. 8.
 98' 1분"
      Coal, mostly attrital with badly crushed and broken
      zone probably high in fusain, ½" thick below 98' 4";
      coal dominantly woody below. TE sample No. 9.
 98'11-3/4"
      Coal, about 80% woody with ½" fusain lens below 99' 4"

SLIM BUTTES, HARDING CO., S. DAK. Mendenhall area

Hole 4 (Upper coals)

Location: c S line SW-NE-36-18N-7E Elevation: 3,300 feet

Date cored: 7/8/51 Date described: 8/1/51

Clay, light buff (bentonitic?), semi-fluid plasticity, (not sampled).

22' 84"

Sand modium aminod unconsolidated (not sampled)

Sand medium grained, unconsolidated, (not sampled). 22' 9-3/4"

Clay, light buff, semi-fluid plasticity as above, (not sampled).

23' 4" Clay, shaly, brown, much less plastic than above, (not sampled).

23' 14" (Top of coal)

Coal pulverulent, when broken apart carefully seems

evident it is mostly in place but badly shrunken and Dureau of cracked from underground weathering, outside of core is Mines sample smeared by semi-fluid clay introduced from above. TE )Lab. No. 7/4 sample No. 1 (.044 U).

23' 8½"

Clay, shaly, brown and plastic, small lenticles of light yellow clay possibly from pyritic oxidation at the bottom, (not sampled).

Coal, pulverulent, extremely oxidized and weathered as ) above, light yellow pellets in the coal are probably a )Bureau of result of pyritic oxidation, sample separated into )Mines sample halves by riffling, no reserve sample. TE sample No. 2)Lab. No. (.010 U).

25! 9"

Loss in drilling 7".

241

Clay, light buff to yellow, semi-fluid consistancy, (not sampled).  $26^{1}$   $5\frac{1}{5}$ 

Coal, weathered and too weak to saw but apparently in normal relationship, outside of sample mud smeared, coal washed in water and submitted as TE sample No. 3, (.003 U), no reserve.

26'10±"

2' Conly shale (not sampled)

3' Coaly shale, (not sampled). 27' 1"

Clay shale, gray, slightly silty, bedding irregular with a few coaly lenticles, (not sampled).
27'10"

Hole 4 (cont.)

General Notes: None of the coal in this core was in any way suitable for petrographic investigation and none has been reserved for that reason. It is surprising that such badly weathered and friable coal was cored.

Bureau of Mines Samples:

```

General Notes: Core was received in good condition with practically full recovery and slightly moist as unpacked. Samples will contain little or no excess moisture. One-half the core is included in TE samples 1, 2 and 4; all of the 3/4" band of coal below 332' 4" is included in TE sample 3. One-third of the coal core has been held in reserve. Blocks, chiefly selected to include attrital coal, were cut from reserve part every 6 to 8 inches and stored under water for further petrographic study. The remainder of the coal was crushed and riffled to provide the separate TE samples and increments of the B. of M. sample. By mistake the black clay band at 333'10" was not rejected; it was noted only when a block from the reserve portion was taken for petrographic study and it disintegrated in water.

From field geologists notes: There was difficulty from caving of poorly consolidated White River strata in upper part of this drill hole.

Bureau of Mines Sample D-71570: Interval 333' 7th to 341' llth; loss 0"; Rejected 0"; coal in sample 8' 4th.

```

General Notes: Core was received in good condition with nearly full recovery, slightly moist to surface dry as unpacked. Samples will contain no excess moisture. One-half of the core is included in TE sample No. 1; others include a riffle split of two-thirds of the core passed through one-fourth inch jaw crusher. About one-third of the core is held in reserve; specimens of attrital coal have been stored for preparing thin sections from every 7" to 12". Measurements on the samples do not exactly coincide with coal depths given by the field geologist because of impurities at the top and bottom of the coal. The field geologist notes difficulty in drilling due to unconsolidated beds above the coal. Silty clay was on the drill bit at depth of 372' 9", 100 percent recovery is inferred for the lower lignite bed, but the silty clay beneath was not cored.

STOREST INFORMATION

Hole 18 (cont.)

378'10½"

Coal, sparsely thin to medium banded; possibly slight—)
ly clayey in the bottom inch. TE sample No. 19.

379'5"

Clay, brown, silty with a few small woody fragments in upper 2½"
grading to grayish coloration beneath and somewhat more silty at about 380'.

380' 3½"

General Notes: Core was received in good condition considering the apparent difficulty encountered in a few intervals where the coal was broken or lost in coring. The coal was slightly moist as unpacked and maintained at saturation as nearly as possible during the period of study. Samples probably contain little excess moisture. Qne-half of the core is included in TE sample No. 13. All other TE samples contain about one-third of the core separated as a riffle cut after jaw crushing two-thirds. About one-third of the core is held in reserve; 24 specimens of attrital coal have been stored under water for preparation of thin sections. Measurements on the samples do not exactly coincide with depths as given by the field geologist for reasons difficult to determine. Lowest depth cored according to the field geologist's notes was 380' 2". The  $1 \frac{1}{2}$ " of core apparently extending to greater depth may be occasioned either by spreading of the core in broken parts or from including 2" of cave material beneath 376' 2" as an inadvertent duplication. The field geologist notes, that at the start of every day's drilling 50' to 100' of caving had to be reamed from the hole and that on three occassions the core barrel was stuck from sand caving on it. Under such conditions it is difficult to get better correspondence in measurements than those given above.

### Hole 19 (cont.)

General Notes: Core was received in good condition, moist as unpacked, and samples taken probably retain a slight excess of moisture over bed conditions. One-half the core has been retained as a reserve; Bureau of Mines samples represent halves of the sample increments combined after crushing and riffling TE samples for the intervals indicated. Nine specimens from the core reserve have been stored under water for preparation of thin sections. The upper beds appear to be flat-lying but those below about 379' down to about 388' have an apparent dip up to nearly 20°. Below this the beds are more horizontally disposed again. The significance of these differences in dip is not clear. Measurements are in good agreement with depths given by the field geologist, with slight losses indicated. Laboratory examination shows, however, considerably less coal than was presumed on cursory inspection in the field, dark carbonaceous shale and clay being deceptive under those conditions.

SECUPINAL DESCRIPTION

# SECIPTAY INFORMATION

97

No. 14 (cont.)

Sandstone, clayey, hard, (not sampled).
23' (Bottom of core submitted to Columbus Laboratory).

General Notes: Core was received in moist condition. Coal has highly weathered, pulverulent and crumbly. In spite of this there is little doubt recovery was virtually complete with practically all coal in its original weathered relationship. Sample splits were made without crushing or riffling; one-fourth of the core was reserved at this laboratory, one-fourth included in the Bureau of Mines sample, and one-half was sent to TE laboratory (except for TE sample 1 and 13, special, in which the complete core was included). Samples retained at Columbus not in condition for petrographic study but some solubility and microfossil studies may be possible. These samples were placed in cloth bags, corresponding to the TE sample numbers, with care taken to avoid mixing of different six inch layers.

Bureau of Mines Sample D-69738: Interval  $14^{\circ}$  8" to  $22^{\circ}$  4-3/4"; loss 0"; rejected 1"; coal in sample  $7^{\circ}$  7-3/4".

TE sample No. 2, (.004 U). 601 511 Coal, sparsely to moderately (woody banded, more attri-) tal than above. TE sample No. 3, (.006 U). )Bureau of 61' 5" )Mines sample Coal, moderately to dominantly woody, pyritic nodule 1")Lab. No. diameter in lower part. TE sample No. 4, (.004 U). )D-68868 Coal, moderately woody, core slightly broken at the top) with \( \frac{1}{2} \) pyritic nodule at 63' 2\( \frac{1}{2} \). TE sample No. 5. (.006 U). 631 7½" Coal, moderately medium-banded with 3/8" black plastic clay parting at 63' 11-5/8" (excluded from Bureau of Mines sample). TE sample No. 6, (.009 U). Clay, plastic with grainy texture and tiny root fragments, a few largely woody fragments also present, buff color. TE sample No. 7, (.002 U). 641 819 Clay as above. 651 511

General Notes: Core was received in wet condition smeared with mud. After washing the surface, the core was split in three parts one of which was sent to the TE Laboratory, one to the Bureau of Mines for regular coal analysis, one of which was retained at Columbus. Samples not kept at Columbus were put through ½" jaw crusher to expedite further investigation. A complete sample of the pulverized and broken coal at the top of this core is not available at the Columbus Laboratory.

Locations NW-NW-SW-1-130N-104W Elevation: 3,414 feet Date cored: 7/25/51 Date described: 291 61 Coal apparently banded, possibly mostly attrital, very ) badly weathered, too friable to saw. TE sample No. 1, (.005 U).)Bureau of 301 )Mines sample TE sample No. 2, (.012 U). )Lab. No. 31 1 D-68870 TE sample No. 3, (.016 U). 321 Clay, silty, grading downward to clay siltstone at about 34'. clay and siltstone brown with grainy texture and few small root traces and coaly lenticles. (Not sampled).

General Notes: Apparently nearly all of this very friable much weathered coal was recovered in the core. On the surface the core was badly mud smeared and this mud was mostly removed in the Laboratory by gentle washing and brushing along the top surface. It was examined after the excess water had been allowed to drain then divided into samples listed above. The samples were placed in water in the attempt to further remove adherent clay. Some of the coal dissolved in the water and was decanted with the clay. The residue was dried on toweling overnight and constitutes the solid part of samples submitted. Part of the soluble material was saved in beakers and evaporated to dryness and are submitted with the samples they are derived from to the TE Laboratory. Since this coal is so excessively weathered, the Bureau of Mines analysis is not likely to resemble any ordinary analysis of coal.

The approximately air dried samples after washing differ somewhat from each other. TE sample No. 1 from 29' 6" to 30' has a browner tone than the other two which are quite black. TE sample No. 3 from 31' to 32' has a considerable number of pieces of fairly hard coherent coal in it about  $\frac{1}{2}$ " in diameter. In general one can guess from treating these samples that relatively little woody material is present in this bed of lignite.

Bureau of Mines Sample D-68870: Interval 29' 6" to 32'; loss 0"; rejected 0"; coal in sample 2' 6".

Location SE-NW-NE-2-130N-104W Ele vation: 3,422 feet Date cored: 7/27/51 Date described: 8/1/51 521 3" 9" claystone, brown, coherent, soapy, (not sampled), half of core discarded to conserve space. 531 (Top of coal) 74", coal considerably broken, probably mostly attrital, two blocks removed for petrographic study. TE sample No. 1, (.005 U). 8½" coal possibly 20% woody, somewhat broken, ½" pyritic lens occurs at  $54^{\circ}$   $2\frac{1}{2}^{\circ}$ , about 1/3 reserved for petrographic study. TE sample No. 2, (.006 U). 541 3-3/4" 10" coal about 30% woody, fairly coherent core, 1/3 re-) served for petrographic study. TE sample No. 3. (.005) Bureau of U). )Mines sample 551 1-3/4" )Lab. No. 11½" coal probably less than 20% woody, much broken in )D-68871 the lower part, about 1/3 reserved for petrographic study. TE sample No. 4, (.006 U). 561 1計  $11^{\pm 11}$  coal about 25% woody, 1/3 of core reserved for petrographic study. TE sample No. 5, (.008 U). 571 12" coal about 80% woody, down to 57' 82", lower part principally attrital, pyritic nodules and lenticles (about ½" diameter) at 57' 3" and 57' 7", core coherent, 1/3 reserved for petrographic study. TE sample No. 6, (.006 U). and (base of coal bed) 581 8-3/4" claystone, silty, dark brown in top inch grading below to light brown color with small sandy lenticles and a few coaly streaks. 581 9±11 2-3/4, loss 2-3/4 in interval from 52 3 to 59. 591

General Notes: Core as unpacked at Columbus was quite dry to the touch with no visible moisture. It does not appear to be weathered and blocks for thin sectioning put immediately into water did not immediately slack down so that probably a fair percentage of inherent bed moisture still is retained. Areas of broken coal seem mostly caused by joints that slope obliquely across the coal bed. Larger lumps in the samples were put
